ABSTRACT

An escape wheel is disclosed having a direction of rotation, defining an upstream direction and a downstream direction, that may be configured to be used in an escape mechanism. The wheel may include a hub, a felly mounted to the hub, and at least one tooth disposed radially on the felly. Each tooth may include a stem that terminates in a finger. The finger may include a first part having a first thickness on the side of the felly, and a second part having a smaller second thickness disposed on the side of an end of the finger. The boundary between the first and second parts may define a threshold that is configured to form an oil container together with the face of the second part adjacent thereto.
